Define the symbols used for Unit Vectors and Unit Dyads

Define Unit Vectors and Unit Dyads for however many frames we need for the system. For this example we will use three frames of reference, with the frame **N** being the Newtonian frame. The header **unitVector** must be included. The arguments are **[frame, symbol, direction]**. So unit vector **b[1]=unitVector[B,b,1]** is the vector in the **B** frame in the **1** direction. The unitDyads are double vectors used to describe inertia properties.

```
In[7]:= w[x_] := unitVector[W,w,x]
a[x_] := unitVector[A,a,x]
b[x_] := unitVector[B,b,x]
c[x_] := unitVector[C,c,x]
d[x_] := unitVector[D,d,x]
e[x_] := unitVector[E,e,x]
f[x_] := unitVector[F,f,x]
g[x_] := unitVector[G,g,x]
h[x_] := unitVector[H,h,x]
n[x_] := unitVector[N,n,x]
ww[x_,y_] := unitDyad[w[x],w[y]]
aa[x_,y_] := unitDyad[a[x],a[y]]
bb[x_,y_] := unitDyad[b[x],b[y]]
cc[x_,y_] := unitDyad[c[x],c[y]]
dd[x_,y_] := unitDyad[d[x],d[y]]
ee[x_,y_] := unitDyad[e[x],e[y]]
ff[x_,y_] := unitDyad[f[x],f[y]]
gg[x_,y_] := unitDyad[g[x],g[y]]
hh[x_,y_] := unitDyad[h[x],h[y]]

Rotations

Lets assume the robot has a moving base, shoulder, and three link arm, with wrist1 and 2. It has a 3-2-2-1-2-1 rotation sequence. Starting from the Newtonian frame N we have a 0-rotation to A, then a 0-rotation to B, then a 3-rotation to C, then a 2-rotation to D, then a 2-rotation to E, then a 1-rotation to F, then a 2-rotation to G, then a 1-rotation to H and the tool pointer

Inverse Kinematics

We need to set up nonlinear equations to be solved to find angles and positions given desired pointer tip location and the tool frame orientation.

First clear all the variables of the kinematics. Sometimes this may cause an error if they have not been assigned numbers yet. Ignore the error and proceed.

```
In[185]:= x[t_] = .

Desired and actual tool orientation

Using the generic rotations from above we will assume an Euler: roll-pitch-yaw sequence or an Euler 1-2-3 sequence to construct the desired tool orientation.

```
In[194]:= Cdes[roll_, pitch_, yaw_] := rot3[yaw].rot2[pitch].rot1[roll]

Solve the equations for best first guess at angles and base position

The strategy to solve the inverse kinematics depends on the design of the robot. There are several closed form solutions for industrial robots, see Ch4 of the class textbook by Craig.

First try to lock in initial estimates of the base location and angles ,

$X_{base}, Y_{base}, Q_1, Q_2, Q_3, Q_4, Q_5,$ and Q_6 . Since the base can move this has many possible solutions.

The robot reach is defined on a sphere about the base coordinate origin. Need to get the base within reach. The minimum base position with respect to reach sphere is found subject to the constraints that the tool axes should be closely aligned with the desired axes and that the joint angles have physical limits due to collisions with other parts, etc.

First we calculate the radius of the sphere of reach based on just the straight reach of the robot. The scaled pointerLength is subtracted to get closer if needed.
